ABSTRACT

Background: Sirtuins attract high attention considering their properties to reverse molecular hallmarks of aging and age-related disorders. Many secondary plant ingredients (SPI) are known for their sirtuin-activating activities as well as epigenetic regulation of telomers, autophagy, senolysis, DNA repair but also improvement of gut microbiota. Furthermore, prebiotics enhanced butyrate and was shown to interact with SIRT pathways. This study investigated the effects of a drink containing a mix of different SPIs in combination with galactooligosaccharides (GOS) and their effect on SIRT activation, markers of aging relevant mechanisms, and gut microbiota composition in correlation with subjective wellbeing and skin structure appearance.

- increased sirtuin expression
- Modulated gut microbiota composition
- improved skin appearance and beauty aspects
- improved subjective well being
**Methods:** We analyzed gene expression, mtDNA amount, and microbial composition in response to a sirtuin-activating drink in humans compared to a control group consuming a placebo. Food frequency, beauty, and general health questionnaires were asked, and a set of mRNAs and miRNAs were assessed using qPCR analysis. The gut composition was analyzed using Illumnia sequencing.

**Results:** SPI increased \textit{SIRT1}, \textit{SIRT3}, and modulated cell cycle relevant \textit{miR16} and senescence regulating \textit{miR34} expression. Additionally, mtDNA amount was higher in the group consuming the active supplement indicating an improved mitochondrial activity. The combined effect of SPI and GOS lead to an increase of \textit{Actinobacteria}, especially \textit{Bifidobacterium}, but also \textit{Veillonellaceae} which was not observed in the control group. Significant correlations between \textit{SIRT3} expression and the gut microbiota \textit{Bifidobacterium} and \textit{Veillonellaceae} were observed. Additionally, statistical analysis of subjects self-reporting indicated beneficial effects regarding beauty and wellbeing.

**Conclusion:** Our results show that the combination of sirtuins inducing SPI and prebiotic GOS influences molecular pathways counteracting aging, senescence, inflammation, and enhanced groups of gut microbiota which are known to improve the innate and adaptive immune system.

**Keywords:** secondary plant ingredients, prebiotic, Sirtuins, subjective wellbeing, Bifidobacterium

**INTRODUCTION**

Due to their regulatory roles in many pathophysiological conditions sirtuins (SIRTs) attract high attention. In mammals, seven SIRTs (SIRT1-7) have been identified and belong to the nicotinamide adenine dinucleotide (NAD+) dependent histone deacetylases (HDAC) [1-3]. HDAC removes the acetyl group from histones, which causes a condensed chromatin structure, thus results in gene silencing [1-2]. SIRT deacetylately histones and non-histone proteins and have been identified in distinct subcellular localization, thus being involved in multiple physiological processes, namely DNA repair, cell cycle regulation, energy metabolism, neuronal protection, gene expression regulation, and epigenetic activity [1][2][4]. SIRTs, located in the mitochondria are involved in amino- and fatty acid metabolism, oxidative phosphorylation, mtDNA replication, and regulation of anti-inflammatory agents [2-5].

Restrictive diets and their activation of \textit{SIRT1} have been intensively studied \textit{in vitro} and \textit{in vivo}, whereas the latter mostly in animal models than in humans [6]. Nevertheless, SIRT expression increases also in humans following Buchinger fasting guidelines [7]. During nutrition depletion, adenosine monophosphate (AMP) increases and adenosine triphosphate (ATP) decreases within the cell thus activating AMP-activated protein kinase (AMPK) and NAD+, further activates SIRTs expression [8-9].

Secondary plant ingredients (SPI) are a broad range of bioactive botanicals and have been described to mimic this effect, thus defined as SIRT activating compounds (STACS). SPI can activate AMPK or SIRT directly or activating SIRT by targeting nicotinamide phosphoribosyltransferase (NAMPT),
the enzyme in the NAD salvage pathway, which leads to an increased NAD+/NADH ratio [1][3][10]. Other studies show that polyphenols can target AMPK, by increasing the AMP/ATP ratio by interfering with the respiratory chain reaction in mitochondria, thus leading to activation of SIRTs [11]. SPI can also modulate micro RNAs (miRNA) leading to SIRT activation [12-13].

SPI which are defined by their low abundance have been used for centuries in traditional medicine due to their free radical scavenging action, antioxidative, antimicrobial and antiviral capacities. Polyphenolic compounds can therefore reduce cardiovascular risk due to low density lipoprotein oxidation inhibition [1][14][15]. Other SPIs exhibit anticancer, anti-obesity, cardio and neuroprotective effects and prevent type 2 diabetes by increasing insulin sensitivity [1].

Additionally, SPIs modulate gut microbiota (GM) [16]. Besides protecting against pathogens colonization, the GM protects integrity and permeability of the gut barrier and is part of the innate and adaptive immunoregulation. Moreover, the GM has several metabolic functions, such as synthesis of vitamins and short-chain fatty acids, absorption of dietary compounds, regulation of lipid, protein and carbohydrate metabolism and enzymatically modifies SPI bioavailability and healthy effect [16-17]. Age, diet, physical inactivity, stress and drugs are the main factors for GM dysbiosis and are linked to diseases regarding the gastrointestinal tract but also metabolic disorders, like obesity or diabetes [17].

SPIs and prebiotics favor the generation of short-chain fatty acids (SCFAs) and the SIRT expression in the gut mucosa. Both exert anti-inflammatory effects, maintains gut barrier functions and beneficially effects clinical blood parameters [18-20] but are also linked to be neuroprotective and regulate hormones, such as leptin, ghrelin, melatonin and serotonin, thus influencing hunger, satiety and mood [21-22]. Nevertheless, the range of short chain fatty acid (SCFAs) activities are limited comparing SPIs metabolites produced, within the gut[23]. Additionally, SPIs are usually found in combination in nature. Due to their heterogeneity, they exhibit different biologic activities and show synergistic properties [23].

Based on their multiple biological benefits and as potential STACs they are nowadays used in nutraceuticals or functional foods and in cosmetics to treat multiple (skin) aging signs [14][24][25]. We conducted a randomized, placebo-controlled, one blinded study to investigate if the SIRTFOOD®SHOT supplement, consisting of several potential natural SIRT activating compounds and SCFA producing prebiotic galactooligosaccharides (GOS) can address SIRTs expression in humans. Additionally, we observed the changes in the microbial gut composition, Food frequency questionnaire outcomes, regarding general health and beauty aspects and possible connections.

MATERIALS AND METHODS

Experimental design: 150 people were enrolled for the study performed at the University of Vienna, Department for nutritional science. The study was randomized, controlled, single-blinded and consists of two intervention groups: SIRTFOOD®SHOT supplementation (active) and placebo/control. The supplement was composed by the Swiss company System-Biologie AG (Wollerau). After dropouts, 100 participants attended the active group and 31 participants were consuming placebos, considering them as the control group. Dropouts were only seen in the intervention group, due to the lower
tolerability of the bitter taste. The subjects were in average 41.12 years. The mean BMI was 26.0219 ± 4.54906 kg/m² and weight 75.993 ± 15.6306kg. 39 participants (29.8%) were male and 92 participants (70.2%) were female. Exclusion criteria were participants taking pre- and probiotics, antibiotics, or sirtuin-activating compounds/medicine like metformin were excluded. Both groups were advised to keep their lifestyle and nutritional habits during the intervention. Only one flacon (25ml) of SIRTFOOD®SHOT or placebo had to be included during the day for three consecutive months. Following compounds can be found in one falcon (25ml) SIRTFOOD®SHOT: 3.5 mg of gallic acid, 40 mg EGCG, 25 mg phloretin, 14 mg anthocyanin, 10 mg anthocyanidins, 6.4 mg oleuropein and 0.9 mg sulforaphane, 3g galactooligosaccharides. The compounds were extracted from mango, apple, blueberry, olive leaves, broccoli, and green tea.

Sample collection and preparation: Food frequency questionnaires, general health and beauty questionnaires, dried blood spots, and stool samples were collected at two different time points at the beginning and after the intervention. In accordance with the declaration of the Viennese Human Ethics committee, all study participants gave written consent for the use of data. The beginning of the intervention is defined as time point 1 (T1) and T2 defines the end of the study.

Nutritional behavior and subjective well-being were validated via several standardized questionnaires. Total DNA and RNA were isolated from dried blood spots (DBS) using MagMAX FFPE DNA/RNA ultra-kit (Thermofisher, USA) via KingFisher Duo Prime purification system. Quantity and quality were assessed using a Nanodrop ND-1000 spectrophotometer (Nanodrop, Wilmington, DE, USA). Relative mitochondrial DNA content was determined in genomic DNA isolated from the dried blood spots using a StepOne Plus real-time PCR Detection System (Applied Biosystem). For PCR, single-copy gene primers, mitochondrial primers (Biomers, Germany) and a LightCycler® 480 Sybr®Green I master mix (Roche) were used. cDNA was done eighter using LunaScript RT SuperMix Kit (Biolabs, Germany) for mRNA or TaqMan Advanced miRNA cDNA synthesis kit for miRNAs. miRNA and mRNA of interest were determined using commercial primers (Thermofisher, USA) and TaqMan Fast advanced Mastermix (Thermofisher, USA) for RT-qPCR amplifications performed on StepOne Plus real-time PCR Detection System (Applied Biosystem). Fold change was calculated using the formula of 2−ΔΔCt (ΔCt= Ctgene of interest - Cthousekeeper; ΔΔCt= ΔCtt2-ΔCtt1 or ΔΔCt= ΔCt -ΔCtmean placebo control) [26] [7]. Samples were generally run in 10 μL reactions in doubles. Upon sample collection, stool samples were stored at -80°C. For sequencing microbial composition all fasting samples were analyzed by Biomes NGS GmbH (Germany) using Illumina Sequencing, written elsewhere [7] [27]

Statistical analysis: Raw microbial sequences were processed using the Quantitative Insights Into Microbial Ecology (QIIME) pipeline [28]. Taxonomy was assigned using the Ribosomal Database Project (RDP) classifier against Greengenes database. All data are presented as mean ± standard deviation (SD). Data were analyzed using IBM SPSS Statistics for Windows Version 22.0 (IBM Corp., Armonk, NY, USA) and graph pad prism (Version 6). Paired t-test was used to compare the different time points for parametric and Wilcoxon test for nonparametric values.
RESULTS

Population characteristics: The total study population size was 131 participants, divided into two different groups. The SIRTFOOD®SHOT group consists of 100 participants, consuming an active supplement, whereas 31 subjects were addressed as a control group, consuming the placebo shot. Males and females were almost normally contributed between the groups, although more females were interested to attend the study. Subjects were between 21 and 67 years, as well in the SIRTFOOD®SHOT as the placebo group. Although most characteristics were equal between the groups, participants in the control group had lower BMI (Table 1).

Table 1: Characteristics of the study population. Values were either given in total number (N) and percentage or mean ± standard deviation (SD)

Subjective well-being and beauty aspects: All participants were asked to interpret their skin appearance before and after the intervention. The placebo study population did not see any beneficial effects regarding beauty aspects. Study participants who consumed the active product had the impression of improved skin texture and its appearance. After the intervention period, 13% of the SIRTFOOD®SHOT population complained less about dry skin (Figure 1a). Moreover, 7.66% stated improved appearance of their skin (Figure 1b), including finer pores (9.63%) (Figure 1c) and fewer wrinkles (3.65%) (Figure 1d). At T1 30% of the SIRTFOOD®SHOT population have stated to have brittle nails (Figure 1e). Thus 14.72% mentioned faster nail growth (Figure 1f), brittle nails deceased of 13% (Figure 1e). Moreover, 34% of the active group population stated a faster hair growth due to the intervention (Figure 1g), consequently, 21.9% reported less hair loss (figure 1h). General health aspects were collected of the total study population. After the intervention period, 38% of the SIRTFOOD®SHOT group reported to feel healthier (Figure 2a) and 43% felt more energy (Figure 2b), due to supplementation. Moreover, almost a quarter of the intervention group stated improved sleep (Figure 2c) and digestion (Figure 2d).
Figure 1. Analysis of questionnaire regarding beauty aspects. All results were given in percentage (%) of total answers of the SIRTFOOS®SHOT group. Figure 1a-f compared the answers of this study population between T1 and T2, whereas figure 1g and h illustrates the results at the end of the timepoint. The impression of dry skin decreased between T1 and T2 (Figure 1a). After the intervention, 7.66% more subjects consuming the active shot stated a better appearance of the skin (Figure 1b), including finer pores and fewer wrinkles (Figure 1c and 1d). Thus 14.72% mentioned faster nail growth (Figure 1f), brittle nails deceased of 13% (Figure 1e). 34% of the active group population stated a faster hair growth due to the intervention (Figure 1g), consequently, 21.9% reported less hair loss (figure 1h).
Figure 2. Analysis general health questionnaire. All results were given in percentage (%) of total answers of the SIRTFOOS®SHOT group. 38% reported to feel healthier (Figure 2a) and 43% felt more energy after the intervention (Figure 2b). Moreover, almost a quarter of the intervention group stated improved sleep (Figure 2c) and digestion (Figure 2d), due to the supplementation.

Mitochondrial DNA content and gene expression:
Higher mtDNA content could be detected in the SIRTFOOD®SHOT intervention compared to the control group, although only a statistical trend (Figure 3a). Moreover, changes in gene expression were seen after SIRTFOOD®SHOT supplementation. Lower miR34a-5p (Figure 3b) and increased miR16-5p (Figure 3c) expression were seen in the SIRTFOOD®SHOT group. Moreover, this study population showed different expression levels of MLH1, SIRT3 and SIRT1 compared to the control (figure 3d-f). Nevertheless, MLH1 and SIRT1 (Figure 3g) gene expression significantly increased and miR34a-5p significantly decreased after supplementation (data not shown).
Figure 3: Results gene expression analysis. The results are expressed as mean +/- SD. Statistical significance between placebo and SIRTFOOD®SHOT (Figure 3a-f) and T1 and T2 of the SIRTFOOD®SHOT intervention (Figure 3g) was determined using paired t-test for parametric values and Wilcoxon test for nonparametric values.
**Gut microbiota composition:** After SIRTFOOD®SHOT supplementation changes in the gut microbiota were observed. At the phylum level of *Tenericutes, Lentisphaerae, Bacteroidetes, Euryarchaeota, Lentisphaerae* and *Actinobacteria* increased, whereas only latter showed a strong statistical trend (Figure 4a). Decreased abundance of *Cyanobacteria, Elusimicrobia, Proteobacteria, Verrucomicrobia, TM7* and *Fusobacteria* were observed after supplementation (Figure 4a). No changes were detected in *Firmicutes* abundance (Figure 4a). The same effects as observed in the Supplementation group were observed for *Euryarchaeota, Lentisphaeae, Cyanobacteria, Elusimicrobia, Proteobacteria, Verrucomicrobia* and *Firmicutes* in the control group (Figure 4b). Contrary to the SIRTFOOD®SHOT group, no significant changes were seen in the abundance of *Actinobacteria, Bacteroidetes, TM7*. The amount of *Tenericutes* decreased (Figure 4b), whereas not statistically tested. In addition, at species level, no significant changes were detected for the placebo group (figure 4d), whereas *Bifidobacterium* increased in the intervention group, although only as a strong trend (figure 4c). *Veillonellaceae* increased for the SIRTFOOD®SHOT (Figure 4e) group but not for the placebo (Figure 4f). All SCFAs propionate, acetate and butyrate only increased slightly (data not shown).
Figure 4. Microbial changes before and after treatment. Gut microbial changes before and after the treatment at phylum level showing *Bifidobacterium* and *Veillonellaceae* with the greatest change. Boxplot graphics demonstrating the elevation of *Bifidobacterium* before and after the intervention comparing to the placebo group, although only a trend $p=0.06$ for the SIRTFOOD®SHOT (c&d). *Veillonellaceae* changes are demonstrated in figure e and f. The results are expressed as mean +/- SD. Statistical significance between T1 and T2 was determined using paired t-test for parametric values and Wilcoxon test for nonparametric values.

**Correlations gut microbiota and gene expression:**
Several correlations were obtained regarding gene expression and different gut microbiota members. *MLH1* and *Veillonellaceae*, in addition SIRT3 and *Actinobactera* especially *Bifidobacterium* significant positive correlations were seen ($p<0.05$) (Figure 5a-c). Increasing SIRT3 negatively correlated with *Bilophila* amount, although not statistically significant (Figure 5d).
Figure 5: Pearson’s correlations between microbiota and gene expression. a) positive correlation between MLH1 and Veillonellaceae (p=0.049). Positive correlation between SIRT3 and Actinobacteria (b), especially Bifidobacterium (c) (p<0.05). SIRT3 and Bilophila negatively correlated, although only a trend (d) (p= 0.07).
DISCUSSION
The human gut microbiota is a dynamic system that is influenced by its host lifestyle, genetics and epigenetics. The human genome and gut microbiome networking within metabolic pathways directly influence both normal physiology and disease processes[29]. SPIs and galactooligosaccharides exhibit prebiotic effects, which have beneficial immune, metabolic and cognitive functions [23]. The short chain fatty acids (SCFAs) produced by the gut microbiota are known to inhibit class I Histone deacetylases (HDACs) and also activate the UCP2-AMPK-acetyl-CoA carboxylase (ACC) pathway with decreased PPARγ gene expression, thus resulting in decreased lipogenesis and increased AMP: ATP ratio. Latter induces AMP-activated protein kinase (AMPK) and sirtuins (SIRT) activation, having multiple beneficial effects on human health [23][30].

Improved digestion was reported by the participants after SIRTFOOD®SHOT supplementtion. Kwon et al. investigated the effect of GM on defeation and concluded the increasing amount of Bifidobacterium is associated with increased stool frequency and better defeation [31]. This means increasing the amount of Bifidobacterium, which we observed after the active supplementation, might be helpful for people with obstipation.

Almost half of the participants from our study mentioned to feel healthier, having more energy, and better sleep after SIRTFOOD®SHOT treatment. Although, these results reflect subjective well-being, SPI and GM metabolites are known to exhibit anti-inflammatory, cardio- and neuroprotective properties and influence metabolism [23]. Via methoxyindole pathway, the gastrointestinal tract is responsible for 95% of bodies serotonin synthesis from dietary tryptophan and is transported via the blood-brain barrier [23]. Because microbial composition is individual, metabolism and health effect can differ within individuals. Due to their prebiotic effect and modulation of GM, SPI supports tryptophan synthesis, the precursor of serotonin [23]. SPI favor the growth of beneficial GM, like Bifidobacterium, which we observed after SIRTFOOD®SHOT treatment but not in the control [17]. Bifidobacterium acts probiotic and Tian et al. [32] reported serotonin enhancement via modulating tryptophan biosynthesis pathways after Bifidobacterium supplementation [33][32]. Additionally, GM and its metabolites influence the sleep duration and quality of its host by influencing clock gene expression. Bifidobacterium has been found to improve the subject’s sleep, both factors increased in our study [34]. Short sleep and bad quality are associated with GM dysbalance and counteract age-related diseases and increased mortality [34].

GM and its modulation by SPI play an important role in mood and gut health. Nevertheless, the host body is a fine-tuning network of many factors and epigenetic mechanisms play an essential role in gene expression thus human health. Thus, participants self-reported better well-being and sleep, this might also be explained by the increased miR16-5p expression in the SIRTFOOD®SHOT group compared to the placebo group. MiR16-5p can be modulated by SPIs [13][35] and regulates not only gut health by targeting claudin 2, which latter is predominantly expressed in leaky epithelia and upregulated in participants with bowel dysfunction [36]. Additionally, host miRNA can enter bacterial cells and regulate growth behavior and certain bacterial gene transcripts [37]. MiR16-5p, which decreases within age [38] is also an important regulator of the cell cycle, but also of serotonin thus regulating mood,
satiety and sleep, factors protective against depression, eating disorders, and aging [39].

SPIs also impact miR34a-5p, involved in the regulation of senescence. Additionally, overexpression is known to silence SIRT1 mRNA expression [40][41]. Obesity is associated with elevated miR34a-5p levels thus resulting in decreased SIRT1 expression. SIRT1 and SIRT3 enhance mitochondrial function, oxidative metabolism and counteract obesity [42]. Interestingly, the SIRTFOOD®SHOT group showed increased mitochondrial DNA amount compared to the control group. Weight loss (data not shown) was the same in both groups with an average -0.5 kg after three months, thus more studies are needed to investigate sirtuins counteract obesity via weight loss in humans.

SIRT can also be expressed in human gut epithelial cells. Khalili et al. [19] reported a significant increase of SIRT1 expression after probiotic supplementation with Lactobacillus casei in participants with type 2 diabetes [19]. The same connections were seen in our study. A higher amount of SIRT3 expressed were seen with increased amount of Actinobacteria, especially Bifidobacterium. All three biomarkers were elevated after SIRTFOOD®SHOT treatment but not with the placebo. Interestingly, Chen et al [43] demonstrate, mice lacking SIRT3 leads to gut dysbiosis, intestinal permeability and inflammation following a high fat diet [43]. Additionally, Natividad et al. [44] reported increased amount of Bilophila after high fat diet in mice, contributing to intestinal barrier dysfunction, inflammation, and metabolic syndrome. After SIRTFOOD®SHOT supplementation, we saw lower Bilophila amount correlated with SIRT3 expression, implicating protective properties against metabolic syndrome.

Veillonellaceae increased in the active study population, but not in the control group. This specific group of microbiosa is known to metabolize lactate for energy production, a substrate contributing to fatigue during a physical performance and produced by Bifidobacterium [45][46]. Thus, an increase in the amount of Veillonellaceae may contribute to better physical performance, thus more energy, which the subjects reported. In addition, we observed a correlation between Veillonellaceae and MutL homolog 1 (MLH1). Latter belongs to DNA mismatch repairs and persons hypermethylated of one allele in MLH1, which contributes to lower MLH1 expression, having a predisposition to developing colorectal cancer [47] [48].

Veillonellaceae contribute to hosts adaptive immune system. Gut microbial dysbiosis can release toxins that induce human DNA damage, concurring its mutability, tumor induction and progression in gastrointestinal cancer [49]. EGCG, the polyphenol of green tea can reverse DNA damage [48]. Moreover, SPI can modulate the abundance of Veillonellaceae [50]

SIRTs are mostly known for their longevity related properties, which are all protecting against the hallmarks of aging [51][52] [4]. Based on this knowledge SIRTS are getting more attention to slowing down skin aging processes and develop cosmetics including natural STATs, although bioavailability and skin permeability are restricting factors for use of many potential active substances [25].

Premature skin aging is manifested by accelerated induction of wrinkling, scaling, roughness, dryness, laxity, and hyperpigmentation. After SIRTFOOD®SHOT supplementation up to 10% of the participants reported improved skin appearance, less dryness, finer pores and fewer wrinkles [53]. Even
here the tight network between SPI, GM and Skin aging needs to be highlighted, thus an imbalance in GM leads to dermatological manifestations [54]. This communication is not only via the skin gut axis but also more directly via metastasis of GM and their metabolites in cases of disrupted intestinal barriers, which can be detected in patients’ bloodstream [55] [29]. Besides being antioxidative and prebiotic, SPIs protect against skin aging via several mechanisms, including via SIRT activating, thus reducing inflammation and limit oxidative damage in tissues via SIRT3/SOD pathway in the mitochondria [56]. Additionally, SPI, like EGCG and resveratrol inhibit the collagen degradation enzyme MMP1, leading to wrinkles and tyrosinase, which leads to Hyperpigmentation [53][25].

More than one-third of the active gup reported faster hair and nail growth. Kubo et al. investigated the effect of several polyphenols regarding hair growth in mice. The results show resveratrol and fisetin as the strongest compound promoting hair growth mainly keeping hair follicles in the anagen phase via telomerase reverse transcription[57]. Several other studies investigated the hair growth potential of SPI, like cyanidins or EGCG [58][59] [60].

Many polyphenol-rich botanicals are considered to be adaptogenic: stress-modifying phytochemicals that increase organisms’ nonspecific resistance to stress by increasing their ability to adapt and survive to external stressors and stimuli.

Thus, being one of the first studies investigating the possibility of SIRT activation by a combination of SPI and GOS in human and some outcomes reflect subjective wellbeing via FFQ this study needs to be considered as a pilot study and further interventions would be interesting to prove causality regarding specific mechanisms for a specific aspect.

CONCLUSION

Microbial dysbiosis or SIRT depletion leading to different pathologies, namely e.g. obesity, Alzheimer disease, Cancer, Diabetes type 2, Liver stenosis, depression, skin diseases. The results of the study demonstrating a broad range of beneficial effects in humans by supplementing a synergistic combination of prebiotics. Secondary plant ingredients not only elevate SIRT expression, it modulates gut microbiota and improved subjective wellbeing.
